

§32 cont. Riemann Integration.

Def

The mesh of a partition P is the maximum length of the subintervals. That is, if $P = \{t_0, t_1, \dots, t_n\}$

$$\text{mesh}(P) = \max \{ t_k - t_{k-1} \mid k=1, 2, \dots, n \}.$$

Given a partition P a set of sample points is an ordered set $S = \{x_1, x_2, \dots, x_n\}$ s.t. $x_i \in [t_{i-1}, t_i]$. (Note, it is possible for $x_{i-1} = x_i$.) The Riemann sum of f wrt a partition P and sample set S is

$$R(f, P, S) = \sum_{k=1}^n f(x_k)(t_k - t_{k-1}).$$

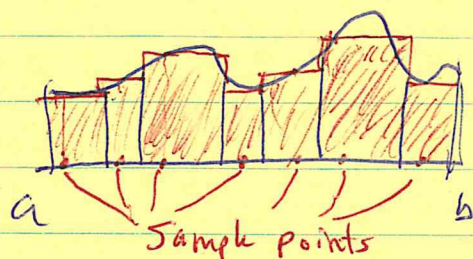

Then f is Riemann integrable over $[a, b]$ if $\exists r \in \mathbb{R}$ s.t.

$\forall \epsilon > 0 \exists \delta > 0$ s.t. $\forall$ partition P with $\text{mesh } P < \delta$ and every ^{possible} sample set

$$|R(f, P, S) - r| < \epsilon.$$

When this happens we write $\int_a^b f = \int_a^b f(x) dx = r$.

Picture of a Riemann Sum

The proof that Riemann and Darboux integrability are equivalent is divided into two Theorems: 32.7 and 32.9. Then ~~the~~ Corollary 32.10 gives a useful tool for computing Riemann integrals.

Thm 32.1 A bdd function f on $[a, b]$ is Darboux integrable if

$$\forall \epsilon > 0, \exists \delta > 0 \text{ s.t. } \text{mesh}(P) < \delta \Rightarrow U(f, P) - L(f, P) < \epsilon.$$

PF Assume this condition holds. Since we can always find a partition P with $\text{mesh}(P) < \delta$, $\exists$ a partition P with $U(f, P) - L(f, P) < \epsilon$ for any $\epsilon > 0$. By Thm 32.5 f is Darboux integrable.

The other direction is not so easy. Suppose f is Darboux integrable on $[a, b]$.

Let $\epsilon > 0$.

Let $P_0 = \{u_0, u_1, u_2, \dots, u_m\}$ be a partition of $[a, b]$ s.t.

$$U(f, P_0) - L(f, P_0) < \frac{\epsilon}{2}$$

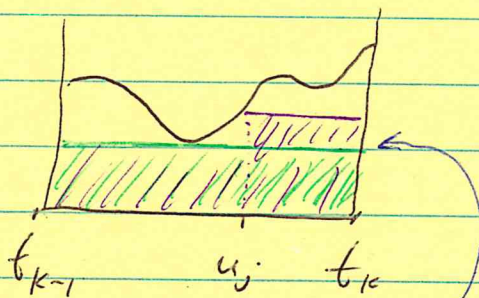

Now, since f is bdd $\exists B > 0$ s.t. $|f(x)| \leq B \forall x \in [a, b]$.

Let $\delta = \epsilon / 8mB$.

Let $P = \{t_0, t_1, \dots, t_n\}$ be a partition of $[a, b]$ with mesh $< \delta$.

Let $Q = P \cup P_0$. We will compare $L(f, Q)$ and $L(f, P)$.

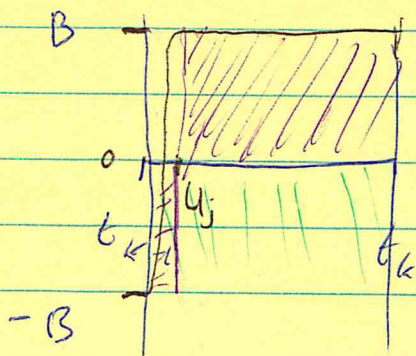

Suppose Q has just one more pt than P . So, just one subinterval has been divided into two.

$L(f, Q)$

$L(f, P)$

$L(f, Q)$ could increase. What is the most it could increase by? The interval has length at most δ . Since $|f(x)|$ is bounded by B , the "worst" that could happen is a gap of $2B$

Thus, $0 \leq L(f, Q) - L(f, P) \leq 2B \cdot \text{mesh } P < 2B\delta$.

If all the points in P_0 are "new", this is over not in P , then Q has m more pts than P . Thus,

$$0 \leq L(f, Q) - L(f, P) \leq m \cdot 2B\delta = \frac{\epsilon}{4}.$$

Since $P_0 \subset Q$ we know $L(f, P_0) \leq L(f, Q)$.

Thus, $L(f, P_0) - L(f, P) < \frac{\epsilon}{4}$. (it could be neg.)

You can show that likewise,

$$U(f, P) - U(f, P_0) < \frac{\epsilon}{4}.$$

Thus, adding these two gives

$$L(f, P_0) - L(f, P) + U(f, P) - U(f, P_0) < \frac{\epsilon}{4} + \frac{\epsilon}{4} = \frac{\epsilon}{2}.$$

$$\Rightarrow U(f, P) - L(f, P) < U(f, P_0) - L(f, P_0) + \frac{\epsilon}{2} < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.$$

Thm 32.9 Let f be a bdd func. on $[a, b]$. Then f is Riemann integrable iff f is Darboux integrable. When these integrals exist, they are equal.

pf Suppose f is Darboux integrable over $[a, b]$.

Let $\varepsilon > 0$. Let $\delta > 0$ be s.t. $\text{mesh } P < \delta \Rightarrow U(f, P) - L(f, P) < \varepsilon$. (★)

Let P be a partition with $\text{mesh} < \delta$. Let S be any sample set for P . We will show

$$|R(f, P, S) - D.I.(f)| < \varepsilon. \quad \odot$$

Then, by definition, the Riemann integral exists and equals the Darboux integral.

From the definitions it is clear that

$$L(f, P) \leq R(f, P, S) \leq U(f, P).$$

$$\text{Now, } U(f, P) < L(f, P) + \varepsilon \leq L(f) + \varepsilon = D.I.(f) + \varepsilon$$

(using (★)) (property of sup)

$$\text{and } L(f, P) > U(f, P) - \varepsilon \geq U(f) - \varepsilon = D.I.(f) - \varepsilon.$$

(★) (inf)

$$\text{Thus, } -\varepsilon < L(f, P) - D.I.(f) < R(f, P, S) - D.I.(f) < U(f, P) - D.I.(f) < \varepsilon.$$

Therefore $\odot$ holds, and this direction is proven.

Now suppose f is Riemann integrable and let $r = R.I(f)$.

We will show that $L(f) \geq r$. You will show that $U(f) \leq r$. It then follows that $L(f) = U(f) = r$ as we will have proven the theorem.

Let $\epsilon > 0$. Let $\delta > 0$ be s.t. $\text{mesh } P < \delta \Rightarrow |R(f, P, S) - r| < \epsilon$.

We are going to choose a special sample set S . Let $P = \{t_0, t_1, \dots, t_n\}$ be a partition of $[a, b]$ with $\text{mesh} < \delta$.

For $k = 1, 2, \dots, n$, choose $x_k \in [t_{k-1}, t_k]$ s.t.

$$f(x_k) < m(f, [t_{k-1}, t_k]) + \epsilon.$$

(We can do this by def. of inf.)

Now,

$$R(f, P, S) \leq L(f, P) + \epsilon(b-a).$$

Also,

$$|R(f, P, S) - r| < \epsilon.$$

Thus,

$$L(f) \geq L(f, P) \geq R(f, P, S) - \epsilon(b-a) >$$

$$\begin{aligned} & r - \epsilon - \epsilon(b-a) \\ & = r - \epsilon(1 + (b-a)). \end{aligned}$$

But, we can make ϵ as small as we wish.

Therefore $L(f) \geq r$ as claimed. (See the handout "Cauchy Sequences (Section 10)", top of page 7 on the ϵ -principle.)
